What's New in the SQLite DLL?

SQLite is a small, compact, and fast database engine. The SQLite core consists of a single C source file (`sqlite3.c`), which gives the whole functionality. It supports "empty" tables, with no records initially. It supports multiple tables with one or more columns in each row. It supports multiple databases, either on the same machine or on different machines. It supports "insert" and "delete" statements to insert or delete records into the database (table), and "update" statements to change the content of existing records. It supports transactions, it automatically commits an entire transaction (set of SQL statements) if everything goes OK, but rolls it back if an error is found. It supports SQL-99 SELECT statements, and it supports the LIMIT clause to restrict the number of records found. It supports foreign keys, both primary and foreign keys. It supports several data types: integer, real, text (string), blob, timestamp, blob-germ, timestamp-germ. The actual database engine uses the memory-mapped-file technique to achieve its high speed. It is designed for a single thread, and does not support transactions if that is what you want. The SQLite3 DLL is designed as a replacement for the SQLiteC/SQLiteD. It is very small, has very few dependencies (only DLLs and one static library), is fully ABI-compatible with the one shipped with the SQLite source code, and it allows you to compile SQLite statically into the application binary. The SQLite3 DLL does not support the full SQL language, only the SELECT and update statements.
