checked Schwann cell
regeneration in
demyelinating lesions of the
peripheral nerve. In this
paper, a detailed light
microscopic and
ultrastructural analysis of
two cases of demyelinating
lesion in the peripheral
nerve is presented. A lesion

developed during the course of acute inflammatory demyelinating polyneuropathy, and a mass was found at the incision site of a neurilemoma. Both showed a marked proliferation of Schwann cells, mainly with the nuclear features of the non-myelinating stage of the cell cycle. It is noted that a significant number of Schwann cell nuclei showed the appearance of a mature nucleus with a normal complement of cytoplasmic organelles. This suggests that schwann cell differentiation is a regulated process rather than a

terminal event, and may indicate that a Schwann cell nucleus in a demyelinating lesion is not necessarily terminal. In a section stained with phospho-antigen, an endoneurial fibroblastic cell that could
